ABSTRACT

In a method and apparatus for predicting process results of objects being processed in a processing chamber of a processing apparatus, operation data and process result data obtained at the time of processing each of the objects are collected and a multivariate analysis performed on the basis of the collected operation data and first obtain correlation process result data to а therebetween. Process results are predicted on the basis Weighting coefficients for the of the first correlation. respective operation data are set on the basis of A second correlation between predicted process results. the weighted operation data and the process result data is obtained by a multivariate analysis. Process results are predicted by using operation data, obtained when objects the objects used to obtain the other than correlation are processed, on the basis of the second correlation.
